## Lecture 7: Sparse LU Factorisation

Simon Etter

2019/2020

# Sparse LU Factorisation

## Recap from previous lectures

Poisson equation in 1D:

- ▶ Tridiagonal system of equations.
- ▶ LU factorisation can be performed in  $\mathcal{O}(n)$  operations and memory.

Poisson equation in 2D:

- ▶ More complicated sparsity pattern.
- ▶ Can LU factorisation still be done efficiently?

Sparsity pattern of two-dimensional discrete Laplacian  $\Delta_n$ .

Every dot represent a nonzero entry of  $\Delta_n$ .

# Sparse LU Factorisation

## Bad news

- ▶ LU factors have more nonzero entries than original matrix.
- ▶ These extra entries in  $L$ ,  $U$  are called *fill-in* and indicated by red dots in picture below.
- ▶ Fill-in significantly increases the memory consumption and workload of sparse LU factorisation.

# Sparse LU Factorisation

## Aim for this lecture

- ▶ Understand how fill-in arises.
- ▶ Find ways to reduce fill-in as much as possible.

## Terminology

Let  $A = \text{sparse}(i, j, v) = LU$  be a sparse matrix with coordinate-list vectors  $i, j, v$ . We introduce the following terms.

- ▶ *Structure of  $A$* : the vectors  $i, j$  but not  $v$ .
- ▶ *Structurally nonzero fill-in entries*:  
entries  $L[i, j]$ ,  $U[i, j]$  which are nonzero for some  $v$ .

In the following, all statements of the form  $A[i, j] \neq 0$  are meant in the structural sense.

# Sparse LU Factorisation

## Example

Consider

$$A_1 := \begin{pmatrix} 1 & & 1 \\ & 1 & 1 \\ & & 1 \\ 1 & 1 & & 1 \end{pmatrix} = \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ 1 & 1 & -2 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ & 1 \\ & 1 \\ & & 1 \end{pmatrix} =: L_1 U_1,$$
$$A_2 := \begin{pmatrix} 1 & & 1 \\ & -1 & 1 \\ & & 1 \\ 1 & 1 & & 1 \end{pmatrix} = \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ 1 & 1 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ & -1 \\ & 1 \\ & & 1 \end{pmatrix} =: L_2 U_2.$$

- ▶  $A_1$  and  $A_2$  have the same *structure*.
- ▶  $L_2[4, 3] = 0$  is *structurally nonzero* since  $L_1[4, 3] \neq 0$ .

# Sparse LU Factorisation

**Graph of a sparse matrix**  $A \in \mathbb{K}^{n \times n}$

Graph  $G(A) := (V(A), E(A))$  defined by

$$V(A) := \{1, \dots, n\}, \quad E(A) := \{j \rightarrow i \mid A[i, j] \neq 0\}.$$

Note transpose in  $E(A)$ : entry  $A[i, j]$  corresponds to edge  $j \rightarrow i$ .

**Path in  $G = (V, E)$**

Ordered sequence  $k_0, \dots, k_p \in V$  such that  $k_{q-1} \rightarrow k_q \in E$  for all  $q$ .  
Number of edges  $p$  is called the length of the path.

**Example**

$$A = \begin{pmatrix} 1 & \bullet & & \\ & 2 & \bullet & \\ \bullet & & 3 & \\ & \bullet & & 4 \end{pmatrix}$$

$2 \rightarrow 1 \rightarrow 3$  is a path of length 2.

# Sparse LU Factorisation

## Path theorem for matrix powers

$$A^p[i, j] \neq 0 \iff \exists \text{ path } j \rightarrow i \text{ of length } p.$$

*Proof.*

$$A^p[i, j] = \sum_{k_{p-1}} \dots \sum_{k_1} A[i, k_{p-1}] \dots A[k_a, k_{a-1}] \dots A[k_1, j].$$

Each term is nonzero iff  $j \rightarrow k_1 \rightarrow \dots \rightarrow k_{p-1} \rightarrow i$  is a path in  $G(A)$ .

## Example (continued)

$$A^2 = \begin{pmatrix} 1 & \bullet & \bullet & \bullet \\ & 2 & \bullet & \bullet \\ \bullet & \bullet & 3 & \bullet \\ \bullet & \bullet & \bullet & 4 \end{pmatrix}$$

$A^2[4, 1] \neq 0$  because  $1 \rightarrow 3 \rightarrow 4$  is a path of length 2 in  $G(A)$ .

$A^2[2, 1] = 0$  because  $1 \rightarrow 3 \rightarrow 4 \rightarrow 2$  is a path of length 3 in  $G(A)$ .

# Sparse LU Factorisation

## Path theorem for matrix inverses

$$A^{-1}[i,j] \neq 0 \iff \exists \text{ path } j \rightarrow i.$$

*Proof.*

- ▶  $A^{-1} = p(A)$  for polynomial  $p(x)$  interpolating  $\frac{1}{x}$  on eigenvalues of  $A$ .
- ▶ Hence entry  $(i,j)$  of  $A^{-1} = \sum_{p=0}^{n-1} c_p A^p$  is nonzero if there is a path  $j \rightarrow i$  of arbitrary length.

## Example (continued)

$$A^{-1} = \begin{pmatrix} 1 & \bullet & \bullet & \bullet \\ \bullet & 2 & \bullet & \bullet \\ \bullet & \bullet & 3 & \bullet \\ \bullet & \bullet & \bullet & 4 \end{pmatrix}$$

$A^{-1}[2,1] \neq 0$  because  $1 \rightarrow 3 \rightarrow 4 \rightarrow 2$  is a path in  $G(A)$ .

# Sparse LU Factorisation

## Corollaries of path theorem

- ▶ If  $G(A)$  is connected (there exists a path between any pair of vertices), then  $A^{-1}$  is dense.
- ▶ If  $G(A)$  is disconnected, i.e.  $A = \begin{pmatrix} A_{11} & 0 \\ 0 & A_{22} \end{pmatrix}$ , then  $A^{-1} = \begin{pmatrix} A_{11}^{-1} & 0 \\ 0 & A_{22}^{-1} \end{pmatrix}$ .
- ▶ Inverse of upper/lower triangular matrix is upper/lower triangular.

# Sparse LU Factorisation

## Fill path

Path  $i \rightarrow k_1 \rightarrow \dots \rightarrow k_p \rightarrow j$  in  $G(A)$  such that  $k_1, \dots, k_p < \min\{i, j\}$ .

## Fill Path Theorem

$$(L + U)[i, j] \neq 0 \iff \exists \text{ fill path } j \rightarrow i.$$

## Example (continued)

$$L + U = \begin{pmatrix} 1 & \bullet & & \\ & 2 & & \bullet \\ \bullet & \bullet & 3 & \\ & \bullet & & 4 \end{pmatrix}$$

$L[3, 2] \neq 0$  because  $2 \rightarrow 1 \rightarrow 3$  is a fill path in  $G(A)$ .

$L[4, 1] = 0$  because  $1 \rightarrow 3 \rightarrow 4$  is not a fill path in  $G(A)$ .

# Sparse LU Factorisation

## Lemma

Let  $i, j \in \{1, \dots, n\}$  and set  $\ell := \{1, \dots, \min\{i, j\} - 1\}$ . Then,

$$\begin{aligned}U[i, j] &= A[i, j] - A[i, \ell] A[\ell, \ell]^{-1} A[\ell, j] && \text{for } i \leq j, \\U[j, j] L[i, j] &= A[i, j] - A[i, \ell] A[\ell, \ell]^{-1} A[\ell, j] && \text{for } i \geq j.\end{aligned}$$

*Proof.* Block LU factorisation with  $\bar{r} := \{\min\{i, j\}, \dots, n\}$ :

$$\begin{pmatrix} A[\ell, \ell] & A[\ell, \bar{r}] \\ A[\bar{r}, \ell] & A[\bar{r}, \bar{r}] \end{pmatrix} = \begin{pmatrix} I & \\ A[\bar{r}, \ell] A[\ell, \ell]^{-1} & I \end{pmatrix} \begin{pmatrix} A[\ell, \ell] & A[\ell, \bar{r}] \\ A[\bar{r}, \bar{r}] - A[\bar{r}, \ell] A[\ell, \ell]^{-1} A[\ell, \bar{r}] \end{pmatrix}.$$

$$\text{Let } L_1 U_1 = A[\ell, \ell], \quad L_2 U_2 = A[\bar{r}, \bar{r}] - A[\bar{r}, \ell] A[\ell, \ell]^{-1} A[\ell, \bar{r}].$$

Full factorisation is then given by

$$\begin{pmatrix} A[\ell, \ell] & A[\ell, \bar{r}] \\ A[\bar{r}, \ell] & A[\bar{r}, \bar{r}] \end{pmatrix} = \begin{pmatrix} L_1 & \\ A[\bar{r}, \ell] A[\ell, \ell]^{-1} L_1 & L_2 \end{pmatrix} \begin{pmatrix} U_1 & L_1^{-1} A[\ell, \bar{r}] \\ & U_2 \end{pmatrix}.$$

Claim follows by noting that  $L[i, j] = L_2[i, j]$  and  $U[i, j] = U_2[i, j]$  have the given form.

# Sparse LU Factorisation

## Fill Path Theorem (repeated from previous slide)

$$(L + U)[i, j] \neq 0 \iff \exists \text{ fill path } j \rightarrow i.$$

*Proof.* Follows immediately from

$$U[i, j] = A[i, j] - A[i, \ell] A[\ell, \ell]^{-1} A[\ell, j] \quad \text{for } i \leq j,$$

$$U[j, j] L[i, j] = A[i, j] - A[i, \ell] A[\ell, \ell]^{-1} A[\ell, j] \quad \text{for } i \geq j.$$

# Sparse LU Factorisation

**Corollary for 2d Laplacian** ( $n \times n$  grid,  $N := n^2$  degrees of freedom)

Memory consumption:

- ▶  $\mathcal{O}(n)$  fill-in per column.
- ▶ Hence,  $\mathcal{O}(n^3) = \mathcal{O}(N^{3/2})$  fill-in overall.

Floating-point operations (FLOPs)

- ▶  $\mathcal{O}(n)$  subdiagonal entries to eliminate per column.
- ▶ Each elimination takes  $\mathcal{O}(n)$  FLOPs.
- ▶ Hence,  $\mathcal{O}(n^4) = \mathcal{O}(N^2)$  FLOPs overall.

# Sparse LU Factorisation

## Observations

Amount of fill-in depends on

- ▶ physical dimension of problem, and
- ▶ ordering of rows and columns.

Can we permute the matrix to reduce fill-in?

# Sparse LU Factorisation

---

**Algorithm 1** Nested dissection ordering

---

- 1: Partition the vertices into three sets  $V_1$ ,  $V_2$ ,  $V_{\text{sep}}$  such that every path from  $V_1$  to  $V_2$  visits at least one vertex in  $V_{\text{sep}}$ .

Subscript  $\text{sep}$  stands for *separator*.  $V_{\text{sep}}$  separates  $G(A)$  into two components.

- 2: Arrange the vertices in the order  $V_1, V_2, V_{\text{sep}}$ , where  $V_1$  and  $V_2$  are ordered recursively according to the nested dissection algorithm.
- 

After reordering:

$$A = \begin{pmatrix} \text{green} & & & & \text{red} \\ & & & & \text{red} \\ & & \text{blue} & & \text{red} \\ \text{red} & \text{red} & & & \text{purple} \end{pmatrix}$$

Note that  $A[V_2, V_1] = A[V_1, V_2] = 0$  due to separator property of  $V_{\text{sep}}$

## Key observation

With this ordering, we have  $L[V_2, V_1] = U[V_1, V_2] = 0$  because any path from  $V_1$  to  $V_2$  must pass through  $V_{\text{sep}}$  and is therefore not a fill-path.

# Sparse LU Factorisation

## Separators for 2d mesh

**Purple** set of vertices: separator at root level.

**Green** sets of vertices: separators after one level of recursion.

**Blue** sets of vertices: separators after two levels of recursion.

**Red** sets of vertices: separators after three levels of recursion.

# Sparse LU Factorisation

## Complexity of LU factorisation with nested dissection ordering

Observations:

- ▶ Diagonal block associated with  $V_{\text{sep}}$  is dense.
- ▶ Factorising this block costs  $\mathcal{O}(|V_{\text{sep}}|^3)$ .

The following can be shown for 2D and 3D meshes (see references):

- ▶ The overall runtime of LU factorisation with nested dissection ordering is dominated by factorisation of largest separator.
- ▶ Nested dissection is asymptotically optimal: no other ordering can outperform nested dissection in the big- $\mathcal{O}$  sense.

# Sparse LU Factorisation

## Complexity of LU factorisation

	Runtime	Memory
$d = 1$	$\mathcal{O}(N)$	$\mathcal{O}(N)$
$d = 2$	$\mathcal{O}(N^{3/2})$	$\mathcal{O}(N \log(N))$
$d = 3$	$\mathcal{O}(N^2)$	$\mathcal{O}(N^{4/3})$

Runtime entries follow immediately from the observation

$$d = 1 \quad \implies \quad |V_{\text{sep}}| = \mathcal{O}(1),$$

$$d = 2 \quad \implies \quad |V_{\text{sep}}| = \mathcal{O}(n) = \mathcal{O}(N^{1/2}),$$

$$d = 3 \quad \implies \quad |V_{\text{sep}}| = \mathcal{O}(n^2) = \mathcal{O}(N^{2/3}).$$

# Sparse LU Factorisation

## **Approximate Minimum Degree (AMD) ordering**

- ▶ Finding good separators can be challenging in practice.
- ▶ AMD is another commonly used ordering which is often easier to compute but equally effective.

## **Sparse algorithms in Julia**

Most functions (e.g. `+`, `*`, `\`, `lu()`) are overloaded to automatically exploit sparsity.

# Sparse LU Factorisation

## Fill-in and pivoting

Recall: LU factorisation of general invertible matrix  $A$  requires pivoting to ensure numerical stability.

Bad news: pivoting may undo the effect of fill-in-reducing orderings.

Good news: some classes of matrices provably do not need pivoting.

## Matrices which do not require pivoting

- ▶ Column-wise diagonally dominant matrices:  $A[j,j] \geq \sum_{i \neq j} |A[i,j]|$ .
- ▶ Symmetric positive semi-definite matrices:  $A = A^T$  and  $v^T A v \geq 0$ .

See Homework Sheet 4.
