Recap: eigenvalues and -vectors of Laplacian

The eigenvalues and -vectors of

$$\Delta_n^{(1)} := (n+1)^2 egin{pmatrix} 2 & -1 & & & & \ -1 & \ddots & \ddots & & \ & \ddots & \ddots & -1 \ & & -1 & 2 \end{pmatrix}$$

are given by

$$\lambda_\ell = (n+1)^2 \left(2\cos\left(\pi\tfrac{\ell}{n+1}\right) - 2\right) \quad \text{and} \quad (u_\ell)_k = \sin\left(\pi\tfrac{\ell k}{n+1}\right)$$

for $\ell \in \{1, \dots n\}$.

Remarks

- ▶ More precisely, we showed $\Delta_n^{(1)} u_\ell = \lambda_\ell u_\ell$.
- ▶ To be certain that u_{ℓ} with $\ell \in \{1, ..., n\}$ are all the eigenvectors, we need to show that they are linearly independent.

Theorem (orthogonality of sin vectors)

The vectors $(u_\ell)_k = \sin(\pi \frac{\ell k}{n+1})$ with $\ell \in \{1, \dots, n\}$ are orthogonal,

$$u_{\ell_1}^\mathsf{T} u_{\ell_2} = \frac{n+1}{2} \, \delta_{\ell_1 \ell_2} := egin{cases} 1 & \text{if } \ell_1 = \ell_2, \\ 0 & \text{otherwise.} \end{cases}$$

Proof of this theorem will be based on lemma on the following slide.

Fundamental lemma of (discrete) Fourier theory

$$\sum_{k=0}^{n-1} \exp \left(2\pi \iota \frac{\ell k}{n} \right) = \begin{cases} n & \text{if } \ell \in n\mathbb{Z} = \{\dots, -n, 0, n, \dots\}, \\ 0 & \text{otherwise.} \end{cases}$$

Proof. Result is obvious for $\ell \in n\mathbb{Z}$. For $\ell \in \mathbb{Z} \setminus (n\mathbb{Z})$, we compute using formula for geometric sums that

$$\sum_{k=0}^{n-1} \exp \left(2\pi \iota \frac{\ell k}{n}\right) = \frac{\exp \left(2\pi \iota \frac{\ell n}{n}\right) - 1}{\exp \left(2\pi \iota \frac{\ell}{n}\right) - 1} = 0.$$

Remark

Continuous version of the above lemma:

$$\int_0^1 \exp(2\pi \iota \ell \, x) \, dx = \begin{cases} 1 & \text{if } \ell = 0, \\ 0 & \text{otherwise.} \end{cases}$$

Proof of orthogonality of sin vectors.

$$\begin{split} u_{\ell_1}^T u_{\ell_2} &= -\frac{1}{4} \sum_{k=1}^n \left(\exp\left(\pi \iota \frac{\ell_1 k}{n+1}\right) - \exp\left(-\pi \iota \frac{\ell_1 k}{n+1}\right) \right) \left(\exp\left(\pi \iota \frac{\ell_2 k}{n+1}\right) - \exp\left(-\pi \iota \frac{\ell_2 k}{n+1}\right) \right) \\ &= -\frac{1}{4} \left(\sum_{k=1}^n \exp\left(\pi \iota \frac{(\ell_1 + \ell_2) k}{n+1}\right) + \sum_{k=1}^n \exp\left(-\pi \iota \frac{(\ell_1 + \ell_2) k}{n+1}\right) \\ &- \sum_{k=1}^n \exp\left(\pi \iota \frac{(\ell_1 - \ell_2) k}{n+1}\right) - \sum_{k=1}^n \exp\left(-\pi \iota \frac{(\ell_1 - \ell_2) k}{n+1}\right) \right) \\ &= -\frac{1}{4} \left(\sum_{k=1}^n \exp\left(\pi \iota \frac{(\ell_1 + \ell_2) k}{n+1}\right) + \sum_{k=1}^n \exp\left(\pi \iota \frac{(\ell_1 + \ell_2) (2n + 2 - k)}{n+1}\right) \right) \\ &- \sum_{k=1}^n \exp\left(\pi \iota \frac{(\ell_1 - \ell_2) k}{n+1}\right) - \sum_{k=1}^n \exp\left(-\pi \iota \frac{(\ell_1 - \ell_2) (2n + 2 - k)}{n+1}\right) \right) \\ &= -\frac{1}{4} \left(\sum_{k=0}^{2n+1} \exp\left(2\pi \iota \frac{(\ell_1 + \ell_2) k}{2(n+1)}\right) - \sum_{k=0}^{2n+1} \exp\left(2\pi \iota \frac{(\ell_1 - \ell_2) k}{2(n+1)}\right) \right) \end{split}$$

Proof of orthogonality of sin vectors (continued).

Main steps on previous slide:

- $Expand <math>\sin(x) = \frac{1}{2\iota} (\exp(x) \exp(-x)).$
- ▶ Rearrange to get terms of the form $\exp\left(\pi \iota \frac{\ell k}{n+1}\right)$.
- ▶ Use $\exp(2\pi\iota) = 1$ and cancellation to go from $k \in \{1, ..., n\}$ to $k \in \{0, ..., 2n + 1\}$.

The result was

$$u_{\ell_1}^T u_{\ell_2} = -\frac{1}{4} \left(\sum_{k=0}^{2n+1} \exp \left(2\pi \iota \frac{(\ell_1 + \ell_2)k}{2(n+1)} \right) - \sum_{k=0}^{2n+1} \exp \left(2\pi \iota \frac{(\ell_1 - \ell_2)k}{2(n+1)} \right) \right).$$

Recall $\ell_1, \ell_2 \in \{1, ..., n\}$.

- ▶ First term is zero since $\ell_1 + \ell_2 \notin 2(n+1)\mathbb{Z}$.
- lacktriangle Second term is zero except if $\ell_1-\ell_2=0$, in which case we obtain

$$u_\ell^T u_\ell = \frac{2n+2}{4} = \frac{n+1}{2}.$$

Sine matrix

$$(S_n)_{k\ell} := \sin\left(\pi \frac{\ell k}{n+1}\right)$$

Corollaries

- ▶ Orthogonality of sin vectors may be written as $S_n^T S_n = \frac{n+1}{2} I$.
- ▶ Eigenvalue equation for 1d Laplacian $\Delta_n^{(1)}$ may be written as

$$\Delta_n^{(1)} = \frac{2}{n+1} \, S_n \, \Lambda_n \, S_n$$

where Λ_n is diagonal matrix given by

$$(\Lambda_n)_{\ell\ell} := (n+1)^2 \left(2\cos\left(\pi\frac{\ell}{n+1}\right)-2\right).$$

Eigenvalue equation for 2d Laplacian $\Delta_n^{(2)}$ may be written as

$$\Delta_n^{(2)} = \tfrac{4}{(n+1)^2} \left(S_n \otimes S_n \right) \left(\Lambda_n \otimes I + I \otimes \Lambda_n \right) \left(S_n \otimes S_n \right).$$

These matrices are orthogonal / diagonal, so inversion is easy!

Vectorisation of matrices

Let $A \in \mathbb{K}^{n \times n}$ be a matrix. Its *vectorisation* $\text{vec}(A) \in \mathbb{K}^{n \times n}$ is obtained by stacking the columns of A into a long vector,

$$\operatorname{vec}(A)_{i+n(j-1)} := A_{ij}.$$

Theorem

Let $A, B, C \in \mathbb{K}^{n \times n}$ be matrices. Then,

$$(A \otimes B) \operatorname{vec}(C) = \operatorname{vec}(ACB^T).$$

Proof. Straightforward but tedious computations.

Solving Poisson equation via sine transform, algorithm

Denote by $f_{k_1k_2}$ the matrix (!) of point-values of f(x, y) on the equispaced $n \times n$ mesh on $[0, 1]^2$.

The corresponding matrix of point-values $u_{k_1k_2}$ of the solution to $-\Delta u = f$ can be computed as follows.

- 1. $\hat{f} := S_n f S_n$
- 2. $\hat{u}_{\ell_1\ell_2} = \frac{\hat{f}_{\ell_1\ell_2}}{-\lambda_{\ell_1}-\lambda_{\ell_2}}$
- 3. $u = \frac{4}{(n+1)^2} S_n \hat{u} S_n$

Rule of thumb for prefactor:

- ▶ Every factor of S_n requires a factor $\sqrt{\frac{2}{n+1}}$.
- ▶ Algorithm above uses S_n four times; hence factor is $\frac{4}{(n+1)^2}$.

Solving Poisson equation via sine transform

Good: only matrix products required.

Bad: $S_n f S_n$ seems to require $\mathcal{O}(n^3) = \mathcal{O}(N^{3/2})$ FLOP. No speedup compared to LU factorisation.

Fast Fourier Transform

Matrix-vector product $S_n v$ with $v \in \mathbb{R}^n$ can be evaluated using only $\mathcal{O}(n \log(n))$ instead of $\mathcal{O}(n^2)$ FLOP!

Similar statements hold for multiplication with

- ▶ Fourier matrix: $F_{k\ell} := \exp\left(2\pi\iota\frac{k\ell}{n}\right)$ for $k, \ell \in \{0, \dots, n-1\}$,
- **cosine matrix**: (similar to S_n , but more complicated boundary conditions).

Corollary

- ▶ $S_n f S_n$ can be computed in $\mathcal{O}(n^2 \log(n)) = \mathcal{O}(N \log(N))$ FLOP.
- ► Even 2d (and 3d) Poisson equation is easy to solve...
- ightharpoonup ... iff $\Omega = [a, b]^d$ and D = const!

The FFTW package

- ► FFTW: Fastest Fourier Transform in the West.
- ► Fastest publicly available code for Fourier and related transforms.
- Available in Julia as a FFTW package.
- ► See 8_fast_fourier_transform.jl on how to use it, and http://www.fftw.org/fftw3_doc/ld-Real_002dodd-DFTs-_0028DSTs_0029.html for documentation regarding sine transform.
